# Physiological responses in rainfed conditions under high density planting system of cotton 

B Santhosh, Ramesh Thatikunta, DVV Reddy, SA Hussain and V Gouri Shankar

#### Abstract

Growth and development physiology of cotton cultivars was studied under drought stress. Study was conducted for two consecutive years i.e., Kharif, 2016-17 and Kharif, 2017-18 in the college farm, College of Agriculture, Rajendranagar, PJTSAU. Results during the boll development stage indicate that photosynthetic rate, stomatal conductance and SCMR were recorded maximum in cultivar WGCV- 48 $\left(26.0 \mu \mathrm{~mol} \mathrm{CO}=\mathrm{m}^{-2} \mathrm{~s}^{-1}, 584 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}\right.$ and 36.2 respectively) and transpiration rate was maximum in NDLH-1938 ( $6.1 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ). WGCV- 48 cultivar showed maximum seed cotton yield (1908 $\mathrm{kg} \mathrm{ha}^{-1}$ ) among all cultivars. Among the spacings studied, $75 \times 10 \mathrm{~cm}$ resulted in maximum photosynthetic rate $\left(25.6 \mu \mathrm{~mol} \mathrm{CO} \mathrm{C}_{2} \mathrm{~m}^{-2} \mathrm{~s}^{-1}\right.$ ), stomatal conductance ( $626 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ), transpiration rate ( $6.15 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ), SCMR (34.7) and seed cotton yield ( $1639 \mathrm{~kg} \mathrm{ha}^{-1}$ ). Enhancement of plant density increased the intra specific competition. Though a slight decrease in boll weight identified, overall yield per hectare increased when compared to conventional system of wide density planting.

Keywords: Cotton, drought, high density planting system and photosynthetic rate

## Introduction

Cotton (Gossypium hirsutum L.) is world's leading fiber crop and as a renewable energy source it ranks second among all oil seed crops. It is being grown in 7 major growing nations worldwide and it plays a significant role in global economy. Drought is one of the most important abiotic factors that threatens the modern agriculture productivity and thereby food security. The productivity of cotton is adversely affected by various abiotic and biotic factors, especially water deficit. Drought tolerance is complex, multi -genic trait, which is governed by several genes. The alteration of this gene complex for breeding tolerance could bring changes in yield potential of plant phenotype because of linkage drag. Therefore morphological, physiological, biochemical and molecular basis of drought tolerance needs to be investigated for development of location specific drought resistant varieties has been taken up.

## Material Methods

The present investigation was carried out at College Farm, College of Agriculture, Professor Jayashankar Telangana State Agricultural University, Rajendranagar, Hyderabad. The farm is geographically situated at $78^{0} 23^{\prime} \mathrm{E}$ longitude and $17^{\circ} 19^{\prime} \mathrm{N}$ latitude and at an altitude of 542.6 m above mean sea level. It falls under Southern Telangana agro climatic zone of Telangana. The following parameters were quantified in the study.
Photosynthetic rate, rate of transpiration, stomatal conductance measurements were made by using Infra Red Gas Analyser (Model TPS-1) from recently fully expanded leaves, at various stages of crop growth when the stress prevailed. The SPAD-502 (Soil Plant Analytical Development) meter was used for measuring the relative chlorophyll content of leaves. The cumulative yield of seed cotton from three pickings in each treatment plot was weighed and expressed in $\mathrm{kg} \mathrm{ha}{ }^{-1}$.

## Results and Discussion Photosynthetic rate

The photosynthetic rate influenced significantly by genotypes and also by plant densities (Table 1). During kharif, 2016, maximum photosynthetic rate was recorded by genotype WGCV-48 under $75 \times 10 \mathrm{~cm}$ spacing at square stage ( $11.0 \mu \mathrm{~mol} \mathrm{CO}_{2} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ), flowering stage ( $16.6 \mu \mathrm{~mol} \mathrm{CO}_{2} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ) and boll development stage ( $25.1 \mu \mathrm{~mol} \mathrm{CO}_{2} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ). Results of Kharif, 2017 also followed similar trend, maximum photosynthetic rate was recorded by
genotype WGCV-48 under $75 \times 10 \mathrm{~cm}$ spacing at square stage ( $11.3 \mu \mathrm{~mol} \mathrm{CO}_{2} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ), flowering stage ( $18.0 \mu \mathrm{~mol} \mathrm{CO}_{2} \mathrm{~m}^{-2}$ $\mathrm{s}^{-1}$ ) and boll development stage ( $26.8 \mu \mathrm{~mol} \mathrm{CO} \mathrm{m}_{2}^{-2} \mathrm{~s}^{-1}$ ). Zhang, 2006 found that photosynthetic rates of cotton at 75100 DAS grown under $60 \times 20 \mathrm{~cm}$ spacing $\left(21.7 \mu \mathrm{~mol} \mathrm{CO}_{2}\right.$ $\mathrm{m}^{-2} \mathrm{~s}^{-1}$ ) is higher than $45 \times 15 \mathrm{~cm}$ spacing ( $20.58 \mu \mathrm{~mol} \mathrm{CO}_{2} \mathrm{~m}^{-2}$ $\mathrm{s}^{-1}$ ) and $45 \times 10 \mathrm{~cm}$ spacing ( $20.82 \mu \mathrm{~mol} \mathrm{CO} \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ). Lawler (1979) ${ }^{[7]}$, reported that net photosynthesis decline in plants subjected to short term moisture stress. Stomata closing in response to moisture stress results in a reduction in leaf photosynthetic capacity resulting in chloroplast dehydration and decreased $\mathrm{CO}_{2}$ diffusion into the leaf (Khan, 2018) ${ }^{[6]}$.

## Transpiration rate

The transpiration rates were found improved due to increased metabolism and better water absorption levels during second season (Table 2). At square formation stage, the combination of WGCV-48 planted under $75 \times 10 \mathrm{~cm}$ spacing had shown maximum transpiration rate ( $5.6 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ) when compared to all other combinations of genotypes and spacings. The combination of genotype NDLH-1938 under $75 \times 10 \mathrm{~cm}$ had shown maximum transpiration rate at flowering stage ( 6.0 $\mathrm{mol} \mathrm{m} \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ) and boll development stage also ( $6.8 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ). Among genotypes studied, WGCV- 48 found to be performing better with respect to transpiration rate during square stage ( $4.8 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ) and is on par with NDLH-1938 ( $4.75 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ). At flowering stage and boll development stages NDLH-1938 $\left(5.3 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}\right.$ and $6.05 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ respectively) performed better among other genotypes. Among plant densities studied, $75 \times 10 \mathrm{~cm}$ had shown higher transpiration rates i.e., $5.15 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ at square stage, 5.65 $\mathrm{mol} \mathrm{m} \mathrm{m}^{-2} \mathrm{~s}^{-1}$ at flowering stage and $6.15 \mathrm{~mol} \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ at boll development stage. The percentage increase of transpiration rate in $75 \times 10 \mathrm{~cm}$ over $60 \times 10 \mathrm{~cm}$ and $45 \times 10 \mathrm{~cm}$ is $8.4 \%$ and $41 \%$ respectively. Stomatal conductance would be a possible indicator for inducing drought tolerance, although a negative correlation is associated between drought resistance and stomata conductance in cotton (Khan, 2018) ${ }^{[6]}$.

## Stomatal conductance

The stomatal conductivity readings of cotton during second season i.e., kharif, 2017 showed an increase in the first crop season (Table 3). WGCV- $48\left(413.5 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}\right)$, was on par with NDLH-1938 ( $403 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ) and found to have better stomatal conductance during square stage. Flowering stage and boll development stages also showed similar trend for stomatal conductance. WGCV-48, which was on par with NDLH-48 showed maximum stomatal conductance during flowering stage ( $634 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ and $621 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ) and boll development stage ( $583.5 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ and $560 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ) respectively. Among plant densities, $75 \times 10 \mathrm{~cm}$ spacing had shown higher stomatal conductance rates at square stage ( $377.5 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ), at flowering stage ( 604 mmol $\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ) and at boll development stage ( $626 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right]$ $\mathrm{m}^{-2} \mathrm{~s}^{-1}$ ). Increase in stomatal conductance during square initiation stage in $75 \times 10 \mathrm{~cm}$ over $60 \times 10 \mathrm{~cm}$ and $45 \times 10 \mathrm{~cm}$ was $9.8 \%$ and $14.9 \%$ respectively.
At square formation stage, the combination of WGCV-48 planted under $75 \times 10 \mathrm{~cm}$ spacing shown maximum stomatal conductance ( $427.5 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ) when compared to all other combinations of genotypes and spacings. The combination of genotype NDLH-1938 under $75 \times 10 \mathrm{~cm}$ had
shown maximum transpiration rate at flowering stage (714 $\mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ) and boll development stage also (744 $\mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ ). This combination is on par with combination of NDLH-1938 planted under $75 \times 10 \mathrm{~cm}$ at square stage, flowering stage and boll development stage (419 $\mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}, 699.5 \mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ and 742.5 $\mathrm{mmol}\left[\mathrm{H}_{2} \mathrm{O}\right] \mathrm{m}^{-2} \mathrm{~s}^{-1}$ respectively). Exposure to mild moisture stress stimulates stomata closure to reduce water loss by regulating transpiration. This reduces stomatal conductance and limits intercellular $\mathrm{CO}_{2}$ concentration (Khan, 2018) ${ }^{[6]}$.

## SPAD meter readings

The SCMR values are good in season indicators of Nitrogen status of plant tissues. SCMR increased upto the stage of boll development in all the studied genotypes during both seasons of study (Table 4). In kharif, 2016 and kharif 2017, maximum SCMR was found by WGCV-48 at square stage (31.8, 32.7), flowering stage $(40.5,38.9)$ and boll development stage (42.8, 29.5). The genotypes differed significantly for SCMR values in both years of study. The difference in SCMR among the cultivars may be attributed to their genetic nature and environmental interactions. At square stage maximum SCMR values were recorded with WGCV-48 (32.3) under $75 \times 10 \mathrm{~cm}$ spacing. Same trend was observed during following phenological stages. The cultivar WGCV- 48 showed maximum SCMR values under $75 \times 10 \mathrm{~cm}$ during flowering stage (39.7) and also during boll development stage (36.2). Among spacings studied, maximum SCMR has been recorded in $75 \times 10 \mathrm{~cm}$ during square stage (31.0), flowering stage (38.4) and boll development stage (34.7). Minimum values were recorded in $45 \times 10 \mathrm{~cm}$ during square stage (27.2), flowering stage (34.0) and boll development stage (32.9). Per cent decrease in maximum SCMR at boll development stage for $75 \times 10 \mathrm{~cm}$ over $60 \times 10 \mathrm{~cm}$ and $45 \times 10 \mathrm{~cm}$ were $3.5,6.0 \%$ and 11.8, $4.4 \%$ during kharif, 2016 and 2017 respectively. Birader, 2013 reported higher SPAD meter readings of cotton at 75 DAS grown under $60 \times 10 \mathrm{~cm}$ spacing (41.5) as compared to $45 \times 10$ (35.4) and $45 \times 15 \mathrm{~cm}$ spacing (37.9). Ronselem, (2012) ${ }^{[8]}$, reported that Mepiquat chloride increased chlorophyll contents (SPAD) in cotton leaves.

## Seed cotton yield ( $\mathrm{kg} \mathrm{ha}^{-1}$ )

Significantly higher seed cotton yield was recorded in $75 \times 10$ cm spacing ( $1639 \mathrm{~kg} \mathrm{ha}^{-1}$ ) over $60 \times 10 \mathrm{~cm}\left(1547 \mathrm{~kg} \mathrm{ha}^{-1}\right)$ and $45 \times 10 \mathrm{~cm}\left(1366 \mathrm{~kg} \mathrm{ha}^{-1}\right)$. The percent rise of seed cotton yield in $75 \times 10 \mathrm{~cm}$ over $60 \times 10 \mathrm{~cm}$ and $45 \times 10 \mathrm{~cm}$ is $6 \%$ and $19.9 \%$ respectively. WGCV-48 (1908 $\mathrm{kg} \mathrm{ha}^{-1}$ ) recorded maximum seed cotton yield and was significantly superior than NDLH1938 ( $1617 \mathrm{~kg} \mathrm{ha}^{-1}$ ). Seed cotton yield in any cultivar is result of cumulative product of boll weight and number of bolls per plant. The better yield in WGCV-48 over other studied cultivars is ascribed to more number of bolls per each plant and also heavier bolls. Ali et al, 2011 reported maximum seed cotton yield ( $2486.2 \mathrm{~kg} \mathrm{ha}^{-1}$ ) in early sown crop under close plant spacing of 15 cm and minimum ( $1762.3 \mathrm{~kg} \mathrm{ha}^{-1}$ ) in wide plant spacing of 45 cm . Jahedi et al., (2013) ${ }^{[5]}$ similarly reported that sympodial branches, individual boll weight and number of bolls per plant were reduced under narrow row spacing ( 30 cm row spacing). Lint yield was found equal or more than in 70 cm row spacing. Row spacing found to have no role yield quality. Thus a plant type with high yield potential, short stature in addition transgenes presence and better fibre properties is preferred in development of ideotype.

Table 1: Photosynthetic rate ( $\mu \mathrm{mol} \mathrm{CO} 2 \mathrm{~m}^{-2} \mathrm{~s}^{-1}$ ) of cotton genotypes as influenced by different spacings in two seasons of crop growth and pooled.

## Conclusion

Better attenuation of light, better competing ability of plants planted in system of $75 \times 10 \mathrm{~cm}$ over $60 \times 10 \mathrm{~cm}$ and $45 \times 10 \mathrm{~cm}$ systems. Imposing of intra specific competition could enhance the abiotic stress tolerance levels in Cotton (Gossypium hirsutum L.).
