Studies on morphological characterization in pigeonpea [*Cajanus cajan* (L.) Millsp] germplasm of Chhattisgarh

Sujit, MK Singh, Neha Belsariya, Luchika Rana, Konreddy Sathish and Vipin Kumar Pandey

Abstract

Pigeonpea [*Cajanus cajan* (L.) Millsp] ($2n = 22$) is an important pulse crop that provide food fodder and variable sources of proteins for poor smallholder farmers in the semi-arid tropics and it can survive in dry environments (Damor *et al.*, 2016; Khoiriyah *et al.*, 2017). In this study 104 germplasm were evaluated and morphological characterization are carried out by visual observation on the basis of DUS characterization, which was conducted in Augmented Randomized Complete Block Design (RBD) with 4 blocks during kharif 2020-2021 at College of Agriculture, Indira Gandhi Krishi Vishwavidyalaya, Raipur, Chhattisgarh. The observation are recorded on five randomly selected plants in each genotype for the following 15 qualitative traits *viz*, Anthocyanin colour on hypocotyls, Flower pattern of streaks on petal, Pod constriction, Pod pubescence, Plant branching pattern, Stem colour, Pod colour, leaf shape, Leaf pubescence on lower surface of the leaf, Pod surface stickiness, Colour of flower base of petal, Plant growth habit, seed colour, seed colour pattern seed shape. The qualitative characters showed wide variation and the potential germplasm may be utilized for further breeding program.

Keywords: Genotype, pigeonpea, genetic diversity, germplasm, qualitative

Introduction

Pigeonpea [*Cajanus cajan* (L.) Millsp] ($2n = 22$) is an important pulse crop which occupies as a major place in Indian agriculture. The seed of pigeon pea is eaten as a green vegetable and dry pulse and is an important source of protein, vitamin B, carotene, and ascorbic acid (Odeny 2007, Choudhary *et al.* 2013) [10, 2]. According to Varshney *et al.* (2010), pigeon pea seeds have 20-22% protein. It is generally planted by smallholder farmers in low input and rainfed conditions (Khouri *et al.* 2015) [6]. Pigeonpea is an often cross-pollinated (20-70%) crop (Saxena, 2006) [11]. Pigeonpea is from the family of ‘Fabaceae’ and is also recognized as ‘Arhar’ or ‘Tur’, usually consumed as *dal* and with rich in dietary protein and nourishment minerals and consumed by almost all Indians. The stem of pigeonpea is used for making local brooms (Kharhara) and baskets. The dry stem of pigeonpea is used as firewood, hedge (badi) and chhani (roof of the hut) in tribal villages. Pigeonpea has an inimitable venue in Indian rural agriculture and India grosses for around 90% of total cultivation. Pigeonpea are most essential legume crop following to chickpea in India. In India, Pigeonpea cultivation is not just the key protein food but also very closely interlinked with the revenue and culture of millions of people and added the status symbol of life, so the “Pigeonpea is widely consumed in the form of *dal* as an economical source of protein.” is most suitable in Indian perspective. It plays a key role in food security, balanced diet subsistence agriculture because of its diverse usage in food, fodder, soil conservation, integrated farming systems and symbiotic nitrogen fixation. Its roots help deliver soil-bound phosphorus to generate it offered for plant development (Arihara *et al.* 1990) [1]. We know that root of pigeonpea breakdown rocks that containing phosphate to provide P available for plant help (Ae *et al.*, 1990) [1]. India has crossed the alarming ‘one billion’ population mark and it is catching up fast the most populous country i.e., China providing significant quantity of quality food to the growing population with limited resources is a big challenge. Characterization has an important role in crop improvement program. To combine the traits in hybridization program and how a newly developed variety is distinct from the existing one can be confirmed through morphological characterization and their comparison. Morphological characterization of monogenic or qualitative traits showed stable performance across the environments whereas polygenic or quantitative traits did not showed stable expressions.

Although pigeonpea improvement through conventional breeding and hybrid technology is on-going, molecular breeding should accelerate utilization of the substantial variability among the pigeonpea landraces and germplasm lines for various morphological, physiological, and agronomic traits.

Methods and Materials

Experimental site and period of experiment

The research was carried out at Research together with Instructional Training Farm, College of Agriculture, Indira Gandhi Krishi Vishwavidyalaya, Raipur, and Chhattisgarh throughout *Kharif* 2020-21. Research place Chhattisgarh are located on 17°14'N and 24°45'N latitudes and 79°16' E and 84°15'E longitudes. capital of the Chhattisgarh state are Raipur and its lies on 21°16'N latitude and 81°36' E longitude with an altitude of 289.60 meters above the mean sea level and the latitude and longitude of experiment field projected at 19° 4'0' N and 82° 2'0' E, respectively.

Experimental season and climatic condition

The area falls underneath central India Hill region and Eastern Plateau (Agro-climatic zone-7) of Chhattisgarh state. It's categorize three parts, were Raipur comes under the Chhattisgarh Plains Zone. Climatic condition of Raipur has a dry sub-humid to semi-dry with 1200-1400 mm average annual rainfall, from the total nearly 85 per cent occurs during rainy season (June to September) and 7-8 per cent remaining received post monsoon duration (October to February). During summer month maximum temperature about high as 48.1°C and during winter (December) minimum occurs at 6°C low temperature. The statistics regarding to minimum and maximum temperatures, evaporation, weekly rainfall, relative humidity, wind velocity and bright sunshine hours during complete crop rises.

Experimental Approaches

The research was conducted in Augmented Randomized Complete Block Design (RBD) with 4 blocks. Pigeonpea germplasm were sown in single lines whereas four checks were replicated in all the blocks to calculate the error and get estimation of blocking effects. The trial seed was sown in 4 blocks and each block included of 25 genotypes and four checks. Spacing of 60 cm between rows and 20 cm between plants were kept. Dose of fertilizer are applied with rate of 20N: 50P: 20K kg/ha. Within the block checks were randomized. For normal growth thinning and gap filling were done that's also maintain plant population in uniform. The regular agronomic performs were implemented for normal crop cultivation.

Observations recorded

During study observations of several agro-morphological and qualitative characters were noted to fulfill the purposes of the study. Random 5 plants from each of pigeonpea genotypes row were observed for remarking data of various characters at guided plant growth stage from guidance of UPOV DUS guidance. Data were from the sampled plants are estimated mean value to different traits were practise to various statistical analyses.

Experimental material

The plant material total of 100 germplasm of Pigeonpea

collected from different parts of Chhattisgarh and 4 checks were used in present study.

Results

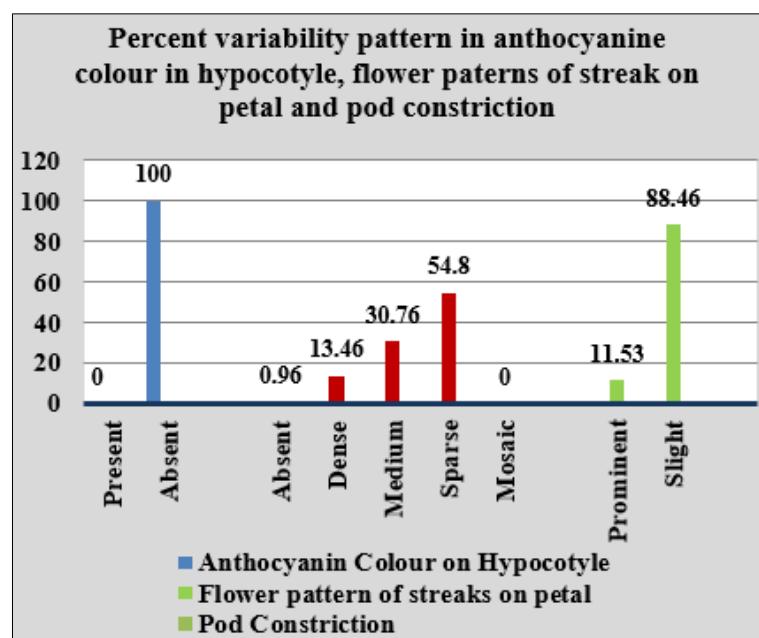

The data of preliminary characterization of 104 accessions of pigeonpea germplasm were recorded for 15 agromorphological characters revealed a wide range of variability in qualitative characters. The range of variability and frequency observed in qualitative characters are given in Table 1. Out of 104 germplasm, in anthocyanin colour on hypocotyls trait (0) germplasm shows present and all (104) germplasm were absent. The plant branching pattern (15) germplasm are erect, (74) germplasm are Semi-spreading and (15) genotypes are spreading were recorded at visual assessment of total (104) germplasm. Plant growth habit trait divided into two categories determinant and in determinants, out of (104) germplasm (74) Determinate and (30) are in determinants were recorded. Stem colour classification were (90) are green and (14) are purple were recorded on the basis of visual assessment from the total (104) genotypes. Leaf shape group (82) are oblong and (22) are narrowly oblong were recorded from entire (104) genotypes of plants. The trait of pubescence on lower surface of the leaf were recorded (0) germplasms present and (104) absent from (104) genotypes. The visual assessment trait Flower colour of base on petal was

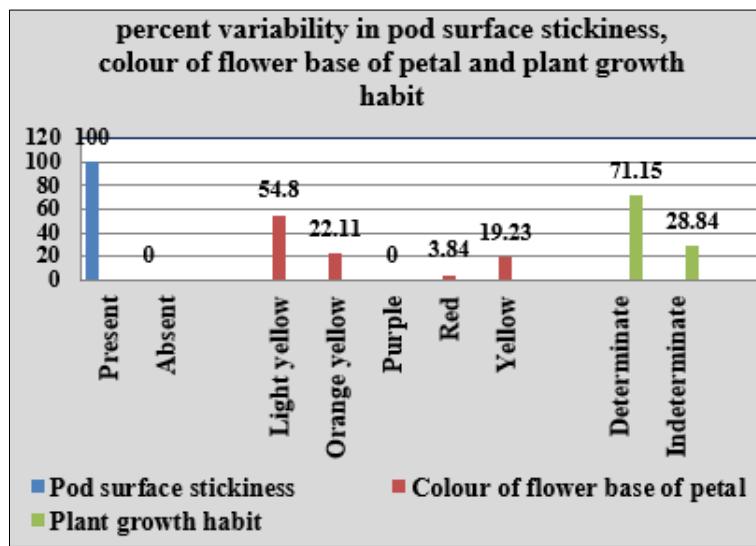

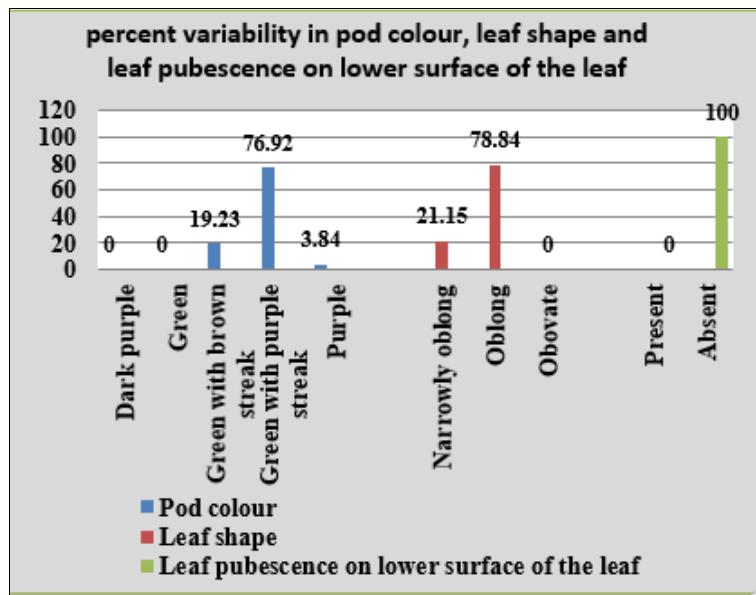

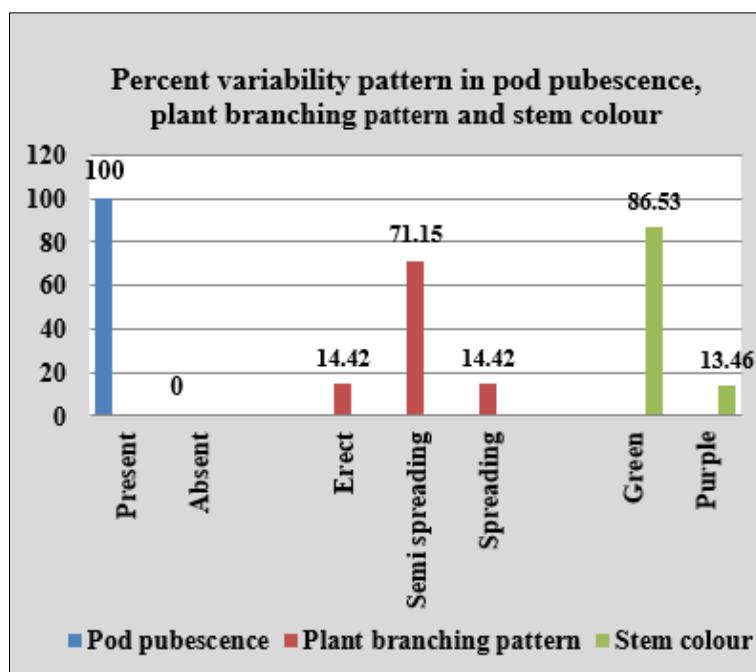

recorded at group of light yellow (57), orange yellow (23), red (4) and yellow (20) genotypes out of (104) germplasms. Flower pattern of streak on petals 1are absent, (57) sparse, (32) medium, (14) dense from (104) total germplasms. The trait of Pod colour noted at (20) green with brown streak, (80) green with purple streak and (4) purple genotypes out of (104) genotypes. The trait of pod pubescence were recorded out of total (104) genotypes, (104) presence and (0) absence based on the hairy like structure present on fully developed green pods. The (104) presence and (0) absence genotypes of pod waxiness were recorded at out of (104) total plant genotype. During experiment (92) slight and (12) prominent type of genotypes of pod constriction was recorded from the entire

(104) genotypes of plants. Pod surface stickiness are divided into presence or absence of stickiness on pod surface, (104) germplasm were presence and (0) absence genotypes were recorded out of the total (104) genotypes. The Seed colour was recorded at ripe seed stage through visual assessment of individual plants that grouped into classes 46 are brown, (39) are dark brown, (6) are grey and (3) genotypes are purple. In seed colour pattern (99) are uniform and (5) genotypes are mottled were recorded on the basis of visual assessment. In seed shape (94) genotypes are oval, (43) are globular and (10) genotypes are elongated out of (104) germplasm, Followed by seed colour pattern, seed colour, seed eye colour, seed shape and seed size as described in Loko *et al.* (2018)^[7].
